Abstract

An attentional mechanism has lately been used to improve neural machine translation (NMT) by selectively focusing on parts of the source sentence during translation. However, there has been little work exploring useful architectures for attention-based NMT. This paper examines two simple and effective classes of attentional mechanism: a *global* approach which always attends to all source words and a *local* one that only looks at a subset of source words at a time. We demonstrate the effectiveness of both approaches over the WMT translation tasks between English and German in both directions. With local attention, we achieve a significant gain of 5.0 BLEU points over non-attentional systems which already incorporate known techniques such as dropout. Our ensemble model using different attention architectures has established a new state-of-the-art result in the WMT’15 English to German translation task with 25.9 BLEU points, an improvement of 1.0 BLEU points over the existing best system backed by NMT and an n -gram reranker.¹

1 Introduction

Neural Machine Translation (NMT) has shown promising results lately, achieving state-of-the-art performances in large-scale translation tasks such as from English to French (Luong et al., 2015) and English to German (Jean et al., 2015). NMT is appealing since it requires minimal domain knowledge and is conceptually simple: the model by Luong et al. (2015) reads through all the source words until the end-of-sentence symbol $\langle \text{eos} \rangle$

Figure 1: **Neural machine translation** – a stacking recurrent architecture for translating a source sequence A B C D into a target sequence X Y Z. Here, $\langle \text{eos} \rangle$ marks the end of a sentence.

is reached. It then starts emitting one target word at a time, as illustrated in Figure 1. NMT is often a large neural network that is trained in an end-to-end fashion and has the ability to generalize well to very long word sequences. This means the model does not have to explicitly store gigantic phrase tables and language models as in the case of standard MT; hence, NMT has a small memory footprint. Lastly, implementing NMT decoders is easy unlike the highly intricate decoders in standard MT (Koehn et al., 2003).

In parallel, the concept of “attention” has gained popularity recently in training neural networks, allowing models to learn alignments between different modalities, e.g., between image objects and agent actions in the dynamic control problem (Mnih et al., 2014) or between visual features of a picture and its text description in the image caption generation task (Xu et al., 2015). In the context of NMT, Bahdanau et al. (2015) has successfully applied such attentional mechanism to jointly translate and align words. To the best of our knowledge, there has not been any other work exploring the use of attention-based architectures for NMT.

In this work, we design, with simplicity and effectiveness in mind, two novel types of attention-

¹All our code and models are publicly available at <http://nlp.stanford.edu/projects/nmt>.

based models: a *global* approach in which all source words are attended and a *local* one whereby only a subset of source words are considered at a time. The former approach resembles the model of (Bahdanau et al., 2015) but is much simpler architecturally. The latter can be viewed as an interesting blend between the *hard* and *soft* attention models proposed in (Xu et al., 2015): it is computationally less expensive than the global model or the soft attention; at the same time, unlike the hard attention, the local attention is differentiable, making it easier to implement and train.² Besides, we also examine various alignment functions for our attention-based models.

Experimentally, we demonstrate that both of our approaches are effective in the WMT translation tasks between English and German in both directions. Our attentional models yield a boost of up to 5.0 BLEU over non-attentional systems which already incorporate known techniques such as dropout. For the English to German translation, we achieve new state-of-the-art (SOTA) results for both WMT’14 and WMT’15, outperforming previous SOTA systems, backed by NMT models and n -gram LM rerankers, by more than 1.0 BLEU. We conduct extensive analysis to evaluate our models in terms of learning, the ability to handle long sentences, choices of attentional architectures, alignment quality, and translation outputs.

2 Neural Machine Translation

A neural machine translation (NMT) system is a neural network that directly models the conditional probability $p(y|x)$ of translating a source sentence, x_1, \dots, x_n , to a target sentence, y_1, \dots, y_m .³ A basic form of an NMT consists of two components: (a) an *encoder* which computes a representation for each source sentence as \mathbf{s} and (b) a *decoder* which generates one target word at a time and hence decomposes the conditional probability as:

$$\log p(y|x) = \sum_{j=1}^m \log p(y_j|y_{<j}, \mathbf{s}) \quad (1)$$

A natural choice to model such a decomposition in the decoder is to use a

²There is a recent work by Gregor et al. (2015), which is very similar to our local attention and applied to the image generation task. However, as we detail later, our model is much simpler and can achieve good performance for NMT.

³All sentences are assumed to terminate with a special “end-of-sentence” token $\langle \text{eos} \rangle$.

recurrent neural network (RNN) architecture, which most of the recent NMT work such as (Kalchbrenner and Blunsom, 2013; Sutskever et al., 2014; Cho et al., 2014; Bahdanau et al., 2015; Luong et al., 2015; Jean et al., 2015) have in common. They, however, differ in terms of which RNN architectures are used for the decoder and how the encoder computes the source sentence representation \mathbf{s} .

Kalchbrenner and Blunsom (2013) used an RNN with the standard hidden unit for the decoder and a convolutional neural network for encoding the source sentence representation. On the other hand, both Sutskever et al. (2014) and Luong et al. (2015) stacked multiple layers of an RNN with a Long Short-Term Memory (LSTM) hidden unit for both the encoder and the decoder. Cho et al. (2014), Bahdanau et al. (2015), and Jean et al. (2015) all adopted a different version of the RNN with an LSTM-inspired hidden unit, the gated recurrent unit (GRU), for both components.⁴

In more details, one can parameterize the probability of decoding each word y_j as:

$$p(y_j|y_{<j}, \mathbf{s}) = \text{softmax}(g(\mathbf{h}_j)) \quad (2)$$

with g being the transformation function that outputs a vocabulary-sized vector.⁵ Here, \mathbf{h}_j is the RNN hidden unit and abstractly computed as:

$$\mathbf{h}_j = f(\mathbf{h}_{j-1}, \mathbf{s}), \quad (3)$$

where f computes the current hidden state given the previous hidden state and can be either a vanilla RNN unit, a GRU, or an LSTM unit. In (Kalchbrenner and Blunsom, 2013; Sutskever et al., 2014; Cho et al., 2014; Luong et al., 2015), the source representation \mathbf{s} is only used once to initialize the decoder hidden state. On the other hand, in (Bahdanau et al., 2015; Jean et al., 2015) and this work, \mathbf{s} , in fact, implies a set of source hidden states which are consulted throughout the entire course of the translation process. Such an approach is referred to as an attention mechanism, which we will discuss next.

In this work, following (Sutskever et al., 2014; Luong et al., 2015), we use the stacking LSTM architecture for our NMT systems, as illustrated

⁴They all used a single RNN layer except for the latter two works which utilized a bidirectional RNN for the encoder.

⁵One can provide g with other inputs such as the currently predicted word y_j as in (Bahdanau et al., 2015).

in Figure 1. We use the LSTM unit defined in (Zaremba et al., 2015). Our training objective is formulated as follows:

$$J_t = \sum_{(x,y) \in D} -\log p(y|x) \quad (4)$$

with D being our parallel training corpus.

3 Attention-based Models

This section describes our various attention-based models which are classified into two broad categories, *global* and *local*. These classes differ in terms of whether the “attention” is placed on all source positions or on only a few source positions. We illustrate these two model types in Figure 2 and 3 respectively.

Common to these two types of models is the fact that at each time step t in the decoding phase, both approaches first take as input the hidden state \mathbf{h}_t at the top layer of a stacking LSTM. The goal is then to derive a context vector \mathbf{c}_t that captures relevant source-side information to help predict the current target word y_t . While these models differ in how the context vector \mathbf{c}_t is derived, they share the same subsequent steps.

Specifically, given the target hidden state \mathbf{h}_t and the source-side context vector \mathbf{c}_t , we employ a simple concatenation layer to combine the information from both vectors to produce an attentional hidden state as follows:

$$\tilde{\mathbf{h}}_t = \tanh(\mathbf{W}_c[\mathbf{c}_t; \mathbf{h}_t]) \quad (5)$$

The attentional vector $\tilde{\mathbf{h}}_t$ is then fed through the softmax layer to produce the predictive distribution formulated as:

$$p(y_t|y_{<t}, x) = \text{softmax}(\mathbf{W}_s \tilde{\mathbf{h}}_t) \quad (6)$$

We now detail how each model type computes the source-side context vector \mathbf{c}_t .

3.1 Global Attention

The idea of a global attentional model is to consider all the hidden states of the encoder when deriving the context vector \mathbf{c}_t . In this model type, a variable-length alignment vector \mathbf{a}_t , whose size equals the number of time steps on the source side, is derived by comparing the current target hidden state \mathbf{h}_t with each source hidden state $\bar{\mathbf{h}}_s$:

$$\begin{aligned} \mathbf{a}_t(s) &= \text{align}(\mathbf{h}_t, \bar{\mathbf{h}}_s) \\ &= \frac{\exp(\text{score}(\mathbf{h}_t, \bar{\mathbf{h}}_s))}{\sum_{s'} \exp(\text{score}(\mathbf{h}_t, \bar{\mathbf{h}}_{s'}))} \end{aligned} \quad (7)$$

Figure 2: **Global attentional model** – at each time step t , the model infers a *variable-length* alignment weight vector \mathbf{a}_t based on the current target state \mathbf{h}_t and all source states $\bar{\mathbf{h}}_s$. A global context vector \mathbf{c}_t is then computed as the weighted average, according to \mathbf{a}_t , over all the source states.

Here, score is referred as a *content-based* function for which we consider three different alternatives:

$$\text{score}(\mathbf{h}_t, \bar{\mathbf{h}}_s) = \begin{cases} \mathbf{h}_t^\top \bar{\mathbf{h}}_s & \text{dot} \\ \mathbf{h}_t^\top \mathbf{W}_a \bar{\mathbf{h}}_s & \text{general} \\ \mathbf{W}_a[\mathbf{h}_t; \bar{\mathbf{h}}_s] & \text{concat} \end{cases} \quad (8)$$

Besides, in our early attempts to build attention-based models, we use a *location-based* function in which the alignment scores are computed from solely the target hidden state \mathbf{h}_t as follows:

$$\mathbf{a}_t = \text{softmax}(\mathbf{W}_a \mathbf{h}_t) \quad \text{location} \quad (9)$$

Given the alignment vector as weights, the context vector \mathbf{c}_t is computed as the weighted average over all the source hidden states.⁶

Comparison to (Bahdanau et al., 2015) – While our global attention approach is similar in spirit to the model proposed by Bahdanau et al. (2015), there are several key differences which reflect how we have both simplified and generalized from the original model. First, we simply use hidden states at the top LSTM layers in both the encoder and decoder as illustrated in Figure 2. Bahdanau et al. (2015), on the other hand, use the concatenation of the forward and backward source hidden states in the bi-directional encoder

⁶Eq. (9) implies that all alignment vectors \mathbf{a}_t are of the same length. For short sentences, we only use the top part of \mathbf{a}_t and for long sentences, we ignore words near the end.

Figure 3: **Local attention model** – the model first predicts a single aligned position p_t for the current target word. A window centered around the source position p_t is then used to compute a context vector c_t , a weighted average of the source hidden states in the window. The weights a_t are inferred from the current target state h_t and those source states \bar{h}_s in the window.

and target hidden states in their non-stacking unidirectional decoder. Second, our computation path is simpler; we go from $h_t \rightarrow a_t \rightarrow c_t \rightarrow \tilde{h}_t$ then make a prediction as detailed in Eq. (5), Eq. (6), and Figure 2. On the other hand, at any time t , Bahdanau et al. (2015) build from the previous hidden state $h_{t-1} \rightarrow a_t \rightarrow c_t \rightarrow h_t$, which, in turn, goes through a deep-output and a maxout layer before making predictions.⁷ Lastly, Bahdanau et al. (2015) only experimented with one alignment function, the *concat* product; whereas we show later that the other alternatives are better.

3.2 Local Attention

The global attention has a drawback that it has to attend to all words on the source side for each target word, which is expensive and can potentially render it impractical to translate longer sequences, e.g., paragraphs or documents. To address this deficiency, we propose a *local* attentional mechanism that chooses to focus only on a small subset of the source positions per target word.

This model takes inspiration from the tradeoff between the *soft* and *hard* attentional models proposed by Xu et al. (2015) to tackle the image caption generation task. In their work, soft attention

refers to the global attention approach in which weights are placed “softly” over all patches in the source image. The hard attention, on the other hand, selects one patch of the image to attend to at a time. While less expensive at inference time, the hard attention model is non-differentiable and requires more complicated techniques such as variance reduction or reinforcement learning to train.

Our local attention mechanism selectively focuses on a small window of context and is differentiable. This approach has an advantage of avoiding the expensive computation incurred in the soft attention and at the same time, is easier to train than the hard attention approach. In concrete details, the model first generates an aligned position p_t for each target word at time t . The context vector c_t is then derived as a weighted average over the set of source hidden states within the window $[p_t - D, p_t + D]$; D is empirically selected.⁸ Unlike the global approach, the local alignment vector a_t is now fixed-dimensional, i.e., $\in \mathbb{R}^{2D+1}$. We consider two variants of the model as below.

Monotonic alignment (local-m) – here, we simply set $p_t = t$ under the assumption that source and target sequences are roughly monotonically aligned and the alignment vector a_t is defined according to Eq. (7). This model is differentiable.⁹

Predictive alignment (local-p) – instead of assuming monotonic alignments, our model predicts an aligned position as follows:

$$p_t = S \cdot \text{sigmoid}(\mathbf{v}_p^\top \tanh(\mathbf{W}_p \mathbf{h}_t)), \quad (10)$$

here, \mathbf{W}_p and \mathbf{v}_p are the model parameters which will be learned to predict positions; whereas, S is the source sentence length. As a result of the sigmoid, $p_t \in [0, S]$. We then place a Gaussian distribution centered around p_t to favor alignment points near p_t . Specifically, our alignment weights are now defined as:

$$a_t(s) = \text{align}(\mathbf{h}_t, \bar{\mathbf{h}}_s) \exp\left(-\frac{(s - p_t)^2}{2\sigma^2}\right) \quad (11)$$

We use the same align function as in Eq. (7) and the standard deviation is empirically set as $\sigma = \frac{D}{2}$. It is important to note that p_t is a *real* number; whereas s is an *integer* within the window centered at p_t . This model is also differentiable.¹⁰

⁸If the window crosses the sentence boundaries, we simply ignore the outside part and consider words in the window.

⁹*local-m* is the same as the global model except that the vector a_t is fixed-length and shorter.

¹⁰*local-p* is similar to the local-m model except that we

⁷We will refer to this difference again in Section 3.3.

We indicate for each attention model the alignment score function used in parentheses.

embeddings. We follow (Sutskever et al., 2014; Luong et al., 2015) in training NMT with similar settings: (a) our parameters are uniformly initialized in $[-0.1, 0.1]$, (b) we train for 10 epochs using plain SGD, (c) a simple learning rate schedule is employed – we start with a learning rate of 1; after 5 epochs, we begin to halve the learning rate every epoch, (d) our mini-batch size is 128, and (e) the normalized gradient is rescaled whenever its norm exceeds 5. Additionally, we also use dropout for our LSTMs as suggested by (Zaremba et al., 2015). For dropout models, we train for 12 epochs and start halving the learning rate after 8 epochs.

Our code is implemented in MATLAB. When running on a single GPU device Tesla K40, we achieve a speed of 1K *target* words per second. It takes 7-10 days to completely train a model.

4.2 English-German Results

We compare our NMT systems in the English-German task with various other systems. These include the previously state-of-the-art (SOTA) system in WMT'14 (Buck et al., 2014), a phrase-based system whose language models were trained on a huge monolingual text, the Common Crawl corpus. For end-to-end neural machine translation systems, to the best of our knowledge, (Jean et al., 2015) is the only work experimenting with this language pair and currently the SOTA system. We only present results for some of our

attention models and will later analyze the rest in Section 5.

As shown in Table 1, we achieve progressive improvements when (a) reversing the source sentence, +1.3 BLEU, as proposed in (Sutskever et al., 2014) and (b) using dropout, +1.4 BLEU. On the top of that, (c) the global attention approach gives a significant boost of +2.8 BLEU, making our model slightly better than the base attentional system of Bahdanau et al. (2015) (row *RNNSearch*). When (d) using the *input-feeding* approach, we seize another notable gain of +1.3 BLEU and outperform their system. The local attention model with predictive alignments (row *local-p*) proves to be even better, giving us a further improvement of +0.9 BLEU on top of the global attention model. It is interesting to observe the trend previously reported in (Luong et al., 2015) that perplexity strongly correlates with translation quality. In total, we have achieved a significant gain of 5.0 BLEU points over the non-attentional baseline which already includes known techniques such as source reversing and dropout..

The unknown replacement technique proposed in (Luong et al., 2015; Jean et al., 2015) yields another nice gain of +1.9 BLEU, demonstrating that our attentional models do learn useful alignments for unknown words. Finally, by ensembling 8 different models of various settings, e.g., using

different attention approaches, with and without dropout etc., we were able to achieve a *new SOTA* result of 23.0 BLEU, outperforming the existing best system (Jean et al., 2015) by +1.4 BLEU.

System	BLEU
SOTA – NMT + 5-gram rerank (MILA)	24.9
Our ensemble 8 models + unk replace	25.9

Table 2: **WMT’15 English-German results** – NIST BLEU scores of the existing WMT’15 SOTA system and our best one on newstest2015.

Latest results in WMT’15 – despite the fact that our models were trained on WMT’14 with slightly less data, we test them on newstest2015 to demonstrate that they can generalize well to different test sets. As shown in Table 2, our best system has established a *new SOTA* performance of 25.9 BLEU, outperforming the existing best system backed by a NMT and a 5-gram LM reranker by +1.0 BLEU.

4.3 German-English Results

We carry out a similar set of experiments for the WMT’15 translation task from German to English. While our systems have not yet matched the performance of the SOTA system, we have demonstrated the effectiveness of our approaches with large and progressive gains in terms of BLEU as illustrated in Table 3. The *attentional* mechanism gives us +2.2 BLEU gain and on top of that, we obtain another boost of up to +1.0 BLEU from the *input-feeding* approach. Using a better alignment function, the content-based *dot* product one, together with *dropout* yields another gain of +2.7 BLEU. Lastly, when applying the unknown word replacement technique, we seize an additional +2.1 BLEU, demonstrating the usefulness of attention in aligning rare words. With more and better models trained, we hope to close the gap with the SOTA system in the near future.

5 Analysis

We conduct extensive analysis to better understand our models in terms of learning, the ability to handle long sentences, choices of attentional architectures, and alignment quality. All models considered here are English-German NMT systems tested on newstest2014.

System	Ppl.	BLEU
<i>WMT’15 systems</i>		
SOTA – <i>phrase-based</i> (Edinburgh)		29.2
NMT + 5-gram rerank (MILA)		27.6
<i>Our NMT systems</i>		
Base (reverse)	14.3	16.9
+ global (<i>location</i>)	12.7	19.1 (+2.2)
+ global (<i>location</i>) + feed	10.9	20.1 (+1.0)
+ global (<i>dot</i>) + drop + feed	9.7	22.8 (+2.7)
+ global (<i>dot</i>) + drop + feed + unk		24.9 (+2.1)

Table 3: **WMT’15 German-English results** – performances of various systems (similar to Table 1). The *base* system already includes source reversing on which we add *global* attention, *dropout*, *input feeding*, and *unk* replacement.

5.1 Learning curves

We compare models built on top of one another as listed in Table 1. It is pleasant to observe in Figure 5 a clear separation between non-attentional and attentional models. The input-feeding approach and the local attention model also demonstrate their abilities in driving the test costs lower. It is interesting to observe the effect of dropout (the blue +curve): it learns slower than other non-dropout models, but as time goes by, it becomes more robust in terms of minimizing test errors.

5.2 Effects of Translating Long Sentences

We follow (Bahdanau et al., 2015) to group sentences of similar lengths together and compute a BLEU score per group. As demonstrated in Figure 6, our attentional models are more effective than the other non-attentional model in handling long sentences: the translation quality does not degrade as sentences become longer. Our best model (the blue +curve) outperforms all other systems in all length buckets.

Figure 6: **Length Analysis** – translation qualities of different systems as sentences become longer.

Figure 5: **Learning curves of models with additive features** – test cost (ln perplexity) on newstest2014 for English-German NMTs as training progresses.

5.3 Choices of Attentional Architectures

We examine different attention models (*global*, *local-m*, *local-p*) and different alignment functions (*location*, *dot*, *general*, *concat*) as described in Section 3. Due to limited resources, we cannot run all the possible combinations. However, results in Table 4 do give us some ideas about different choices. *Location-based* function does not learn good alignments: the *global (location)* model can only obtain a small gain when performing unknown word replacement compared to using other alignment functions.¹³ For *content-based* alignment functions, our implementation does not yield good performances with *concat* and more analysis should be done to better understand the reason.¹⁴ It is interesting to observe that *dot* works well for the global attention and *general* is better for the local attention. Among the different attention models, the local attention model with predictive alignments (*local-p*) is best, both in terms of perplexities and BLEU scores.

5.4 Alignment Quality

A bi-product of attentional models are word alignments. While (Bahdanau et al., 2015) has tried to visualize alignments for some sample sentences or observe gains in translation quality as an indication of a working attention model, no work has as-

¹³There is a subtle difference in how we retrieve alignments for the different alignment functions. At time step t in which we receive y_{t-1} as input and then compute h_t , a_t , c_t , and \tilde{h}_t before predicting y_t , the alignment vector a_t is used as alignment weights for (a) the predicted word y_t in the *location-based* alignment functions and (b) the input word y_{t-1} in the *content-based* functions.

¹⁴With *concat*, the perplexities achieved by different models are 6.7 (global), 7.1 (local-m), and 7.1 (local-p).

System	Ppl	BLEU	
		Before	After unk
global (location)	6.4	18.1	19.3 (+1.2)
global (dot)	6.1	18.6	20.5 (+1.9)
global (general)	6.1	17.3	19.1 (+1.8)
local-m (dot)	>7.0	x	x
local-m (general)	6.2	18.6	20.4 (+1.8)
local-p (dot)	6.6	18.0	19.6 (+1.9)
local-p (general)	5.9	19	20.9 (+1.9)

Table 4: **Attentional Architectures** – performances of different attentional models. We trained two local-m (dot) models; both have ppl > 7.0.

Method	AER
global (location)	0.39
local-m (general)	0.34
local-p (general)	0.36
ensemble	0.34
Berkeley Aligner	0.32

Table 5: **AER scores** – results of various models on the RWTH English-German alignment data.

essed the alignments learned as a whole. In contrast, we set out to evaluate the alignment quality using the alignment error rate (AER) metric.

given the gold alignment data provided by RWTH for 508 English-German Europarl sentences, we “force” decode our attentional models to produce translations that match the references. We extract only one-to-one alignments by selecting the source word with the highest alignment weight per target word. Nevertheless, as shown in Table 5, we were able to achieve AER scores com-

parable to the one-to-many alignments obtained by Berkeley aligner (Liang et al., 2006).¹⁵

We also found that the alignments produced by local attention models achieve lower AERs than those of the global one. The AER obtained by the ensemble, while good, is not better than the local-m AER, suggesting the well-known observation that AER and translation scores are not well correlated (Fraser and Marcu, 2007). In Appendix ??, we show some alignment visualizations.

6 Conclusion

In this paper, we propose two simple and effective attentional mechanisms for neural machine translation: the *global* approach which always looks at all source positions and the *local* one that only attends to a subset of source positions at a time. We test the effectiveness of our models in the WMT translation tasks between English and German in both directions. Our attention-based NMTs yield large gains of up to 5.0 BLEU over non-attentional models which already incorporate known techniques such as dropout. For the English to German translation direction, our best system has established new state-of-the-art results for both WMT’14 and WMT’15, outperforming existing best systems, backed by NMT models and *n*-gram LM rerankers, by a good margin.

We have compared various alignment functions and shed light on which functions are best for which attentional models. Our analysis shows that attention-based NMT models are superior to non-attentional ones in many cases, for example in translating names and handling long sentences. Lastly, we are first to evaluate the alignment quality of our models using alignment error rates.

Acknowledgment

We gratefully acknowledge support from a gift from Bloomberg L.P. and the support of NVIDIA Corporation with the donation of Tesla K40 GPUs. We thank Andrew Ng and his group members as well as the the Stanford Research Computing people for letting us use their computing resources. We especially thank Russell Stewart for helpful discussions on the models. Lastly, we thank Quoc Le, Ilya Sutskever, Oriol Vinyals, Richard Socher, Michael Kayser, Jiwei Li, Panupong Pasupat, Kelvin Gu, members of the Stanford NLP

Group as well as the anonymous reviewers for their valuable comments and feedback.

English-German translations

src	Orlando Bloom and Miranda Kerr still love each other
ref	Orlando Bloom und <i>Miranda Kerr</i> lieben sich noch immer
best	Orlando Bloom und <i>Miranda Kerr</i> lieben einander noch immer .
base	Orlando Bloom und Lucas Miranda lieben einander noch immer .
src	" We ' re pleased the FAA recognizes that an enjoyable passenger experience is not incompatible with safety and security , " said Roger Dow , CEO of the U.S. Travel Association .
ref	" Wir freuen uns , dass die FAA erkennt , dass ein angenehmes Passagiererlebnis nicht im Widerspruch zur Sicherheit steht " , sagte <i>Roger Dow</i> , CEO der U.S. Travel Association .
best	" Wir freuen uns , dass die FAA anerkennt , dass ein angenehmes ist nicht mit Sicherheit und Sicherheit <i>unvereinbar</i> ist " , sagte <i>Roger Dow</i> , CEO der US - die .
base	" Wir freuen uns über die <unk> , dass ein <unk> <unk> mit Sicherheit nicht vereinbar ist mit Sicherheit und Sicherheit " , sagte <i>Roger Cameron</i> , CEO der US - <unk> .

German-English translations

src	In einem Interview sagte Bloom jedoch , dass er und Kerr sich noch immer lieben .
ref	However , in an interview , Bloom has said that he and <i>Kerr</i> still love each other .
best	In an interview , however , Bloom said that he and <i>Kerr</i> still love .
base	However , in an interview , Bloom said that he and Tina were still <unk> .
src	Wegen der von Berlin und der Europäischen Zentralbank verhängten strengen Sparpolitik in Verbindung mit der Zwangsjacke , in die die jeweilige nationale Wirtschaft durch das Festhalten an der gemeinsamen Währung genötigt wird , sind viele Menschen der Ansicht , das Projekt Europa sei zu weit gegangen
ref	The <i>austerity imposed by Berlin and the European Central Bank , coupled with the straitjacket</i> imposed on national economies through adherence to the common currency , has led many people to think Project Europe has gone too far .
best	Because of the strict <i>austerity measures imposed by Berlin and the European Central Bank in connection with the straitjacket</i> in which the respective national economy is forced to adhere to the common currency , many people believe that the European project has gone too far .
base	Because of the pressure imposed by the European Central Bank and the Federal Central Bank with the strict austerity imposed on the national economy in the face of the single currency , many people believe that the European project has gone too far .

Table 6: **Sample translations** – examples in both translation directions. For each case, we show the source (*src*), the human translation (*ref*), the translation from our best model (*best*), and the translation of a non-attentional model (*base*). We italicize some *correct* translation segments and highlight a few **wrong** ones in bold. See Appendix A for detailed descriptions.

[Xu et al.2015] Kelvin Xu, Jimmy Ba, Ryan Kiros, Kyunghyun Cho, Aaron C. Courville, Ruslan Salakhutdinov, Richard S. Zemel, and Yoshua Bengio. 2015. Show, attend and tell: Neural image caption generation with visual attention. In *ICML*.

[Zaremba et al.2015] Wojciech Zaremba, Ilya Sutskever, and Oriol Vinyals. 2015. Recurrent neural network regularization. In *ICLR*.

A Sample Translations

We show in Table 6 sample translations of both directions. From the examples, it is interesting to observe the effect of attentional models in correctly translating names such as “Miranda Kerr”, “Roger Dow”, and “Kerr”. Non-attentional models, while producing sensible names from a language model perspective, lacks the direct connections from the

source side to make correct translations as with the case of *keattention*-based NMT systems.

We also observed an interesting case in the second English-German example, which requires translating the *doubly-negated* phrase, “not incompatible”. The attentional model produces “nicht ... unvereinbar”, a correct translation; whereas the non-attentional model generates “nicht vereinbar”, meaning “not compatible”.¹⁶ Both models, however, failed to translate “passenger experience”. The attentional model also demonstrates its superiority in translating long sentences as in the second German-English example.

¹⁶The reference uses a more fancy translation of “incompatible”, which is “im Widerspruch zu etwas stehen”.

Figure 7: **Alignment visualizations** – shown are images of the attention weights learned by various models: (top left) global, (top right) local-m, and (bottom left) local-p. The *gold* alignments are displayed at the bottom right corner. The alignment visualizations of the local attention models are much sharper than that of the global one. This contrast matches our expectation as the local models were designed to only focus on a subset of words each time. Also, since we translate from English to German and reverse the source English sentence, the white strides at the words “*reality*” and “.” in the global model reveals an interesting access pattern: it tends to refer back to the beginning of the source sequence.
